Abstract

A combination of implicit and explicit timestepping is analyzed for a system of ODEs motivated by ones arising from spatial discretizations of evolutionary partial differential equations. Loosely speaking, the method we consider is implicit in local and stabilizing terms in the underlying PDE and explicit in nonlocal and unstabilizing terms. Unconditional stability and convergence of the numerical scheme are proven by the energy method and by algebraic techniques. This stability result is surprising because usually when different methods are combined, the stability properties of the least stable method plays a determining role in the combination.

1 Introduction

This report considers timestepping methods for systems of ordinary differential equations of the form

$$u'(t) + Au(t) + B(u)u(t) - Cu(t) = f(t), \tag{1.1}$$

in which A, $B(u)$, and C are $n \times n$ matrices, $u(t)$ and $f(t)$ are n-vectors, and

$$A = A^T \succ 0,\ B(u) = -B(u)^*,\ C = C^T \succeq 0 \text{ and } A - C \succeq 0. \tag{1.2}$$

Here $\succ$ and $\succeq$ denote, respectively, the positive definite and the positive semidefinite ordering. The key properties motivating our work are that A is sparse and that although C is not sparse, the action of C on a vector is inexpensive to calculate. This structure is motivated by multiscale discretizations of turbulence but can also arise from closed-loop control problems and ensemble calculations. Given this structure of (1.1), the simplest scheme that is computationally feasible is explicit in the global, unstable part of (1.1), that is, Cu. Accordingly, we consider

$$\frac{u_{n+1} - u_n}{k} + Au_{n+1} + B(u_n)u_{n+1} - Cu_n = f_{n+1}, k = \Delta t, \tag{1.3}$$

where u_n is the approximation to $u(t = nk)$. Usually when methods are combined, the stability properties of the explicit method play a determining role in the overall method. In Theorems 2.1 and 2.2, we prove the surprising result that (1.3) is unconditionally stable. This result is outside the realm of root condition stability analysis for uncoupled scalar problems.

In Section 2, unconditional stability and convergence of (1.3) are proven. We give two stability proofs. The first is algebraic. Since the constants depend on the dimension of the system, we also give an energy proof of stability (with uniform constants) that is potentially extensible to discretized PDEs. Section 3 presents numerical tests illustrating the theory. First, we briefly summarize some motivating problems leading to (1.1).

The basic model of the turbulent dispersion is that it is dissipative in the mean (see [?], [?], [?]). A more accurate formulation is that its dissipative effects are focused on the smallest resolved scales (see [?]). This physical idea has led to algorithms for numerical stabilization of transport-dominated phenomena based on eddy diffusivity acting only on the smallest resolved scales (e.g., [?], [?], [?], [?], [?], [?], [?], [?], [?]). The natural realization

of this idea for spatial discretizations of convection diffusion equations is diffusive stabilization on all scales and then antidiffusing on the large scales. This leads to the system of ODEs

$$\dot{u}_{ij}(t) + b \cdot \nabla^h u_{ij} - (\epsilon_0(h) + \epsilon)\Delta^h u_{ij} + \epsilon_0(h) P_H(\Delta^h P_H(u_{ij})) = f_{ij}, \quad (1.4)$$

where standard notation is used: Δ^h is the discrete Laplacian, $\epsilon_0(h)$ is the artificial viscosity parameters and P_H denotes a projection onto a coarser mesh; see Section 3 for details. The system (1.4) fits exactly the form (1.1), (1.2), where C is provided as the matrix arising from $\epsilon_0(h)$ term. We shall also test one algorithm as a perturbation of the method (1.4) in which the projection is replaced by a nearest averaging $\overline{\Delta^h \overline{u_{ij}}}$. In both cases, the projection or averaging operator accounts for the nonlocal character (i.e., the large bandwidth) of C. On the other hand, averaging and projection are both embarrassingly parallel operators whose action on a given vector is cheap to perform.

Remark 1.1. *(1) A second main application is discretization of turbulent flow problems which, although nonlinear and constrained, have a similar structure to the above (simple) linear convection diffusion problem.*
(2) A known method of stabilizing the timestepping and the associated linear system (but not the spacial discretization) corresponds to (1.1) without the averaging:

$$\frac{u_{n+1} - u_n}{k} + b \cdot \nabla^h u_{n+1} - (\epsilon_0(h) + \epsilon)\Delta^h u_{n+1} + \epsilon_0(h)\Delta^h u_n = f_{n+1}. \quad (1.5)$$

Each time step requires the inversion of the matrix corresponding the operator $-(\epsilon_0(h)+\epsilon)\Delta^h + b\cdot\nabla^h + k^{-1}I$, which, for ϵ_0 suitably chosen, is an M-matrix. Our analysis applies to this method as well.

2 The Stability Analysis

For our analysis, we assume that $B(u)$ is in $C^1(\Re^n)$ and $f(t)$ is in $C^1([0,\infty))$. For any $T > 0$, we denote by

$$F_T = \max_{t\in[0,T]} \|f(t)\|_2 .$$

Lemma 2.1. *The system of ODEs (1.1) under the condition (1.2) with initial condition $u(0) = u_0$ has a unique solution on $[0, T]$, for any $T > 0$.*

Proof Since (1.1) can be written as $\dot{u} = \psi(t, u)$ with ψ being of class C^0 in t and C^1 in u, local existence and uniqueness follows from the classical theory of ODEs [**?**, Theorem V.8].

We now show that the solution does not experience blow-up and can be extended everywhere. We multiply through (1.1) by $(u(t)^T)$ and we use (1.2) to obtain that

$$u(t)^T u'(t) \leq -u(t)^T (A - C)u(t) + u(t)^T f(t) \leq u(t)^T f(t).$$

Using Cauchy-Schwarz, we obtain that

$$\frac{d}{dt} \|u(t)\|_2^2 \leq \|u(t)\|_2^2 + F_T^2.$$

In turn, this implies that,

$$\|u(t)\|_2^2 \leq \|u(0)\|_2^2 e^t + F_T^2 \left(e^t - 1\right)$$

for any t in an interval containing 0 where $u(t)$ is defined. Since $u(t)$ does not experience blow-up in finite time, it can be extended uniquely over all of $[0, T]$. $\square$

Note that from (1.1) and our assumtion that $f(t)$ is of class $C^1([0, \infty])$, we get that $u(t)$ is of class $C^2([0, \infty])$. The fact that $u''(t)$ is continuous will be used in determining a bound for the truncation error.

Consider the system of ODEs (1.1) under the condition (1.2) and discretized by (1.3).

First, we note that each step of (1.3) requires the inversion of $I + kA + kB_n$.

Lemma 2.2. *Under (1.2) the $n \times n$ matrix $I + kA + kB_n$ has a positive definite symmetric part and is invertible.*

Proof: Let x be any nonzero vector in $\Re^n$. Then

$$\begin{aligned} x^T (I + kA + kB_n)x &= x^T x + kx^T Ax + kx^T B_n x \\ &= \|x\|_2^2 + kx^T Ax > 0. \quad \square \end{aligned}$$

Since A, $B_n = B(u_n)$ and C do not commute, the stability of the numerical scheme cannot be analyzed by reduction to eigenvalues. Therefore, we formulate an energy norm that is not increased at each time step, that is, $\|u_{n+1}\|_E \leq \|u_n\|_E$.

Definition 2.1. *The energy norm of (1.3),* $\|.\|_E$*, is given by*

$$\|u\|_E^{\,2} = u^T u + k u^T C u, \tag{2.1}$$

for some $u \in \Re^n$*, and its associated inner product is* $< u, v >_E = (N_k v)^T (N_k u)$*, with* $N_k = (I + kC)^{\frac{1}{2}}$*, for some* $u, v \in \Re^n$*.*

It can be seem immediately that the energy norm and the 2-norm satisfy the following inequality:

$$\sqrt{1 + k\lambda_{min}(C)} \leq \|u\|_E \leq \sqrt{1 + k\lambda_{max}(C)},$$

where $\lambda_{min}(C)$ and $\lambda_{max}(C)$ are, respectively, the smallest and the largest eigenvalue of C. From this inequality and the positive semidefiniteness of C, we get that the induced matrix norms satisfy

$$\|A\|_E \leq \|A\|_2 \sqrt{1 + k\lambda_{max}(C)}.$$

Theorem 2.1. *Let* u_n *satisfy (1.3) with* $f(.) \equiv 0$*, under the condition (1.2) on the coefficients. Then,*

$$\|u_{n+1}\|_E \leq \|u_n\|_E .$$

Proof: Multiplying with u_{n+1}^T through the equation in (1.3), we obtain

$$u_{n+1}^T \frac{u_{n+1} - u_n}{k} + u_{n+1}^T A u_{n+1} + u_{n+1}^T B_n u_{n+1} = u_{n+1}^T C u_n$$

Since B_n is skew symmetric, $u_{n+1}^T B_n u_{n+1} = 0$. Therefore

$$u_{n+1}^T \frac{u_{n+1} - u_n}{k} + u_{n+1}^T A u_{n+1} = u_{n+1}^T C u_n. \tag{2.2}$$

This is equivalent to

$$u_{n+1}^T u_{n+1} + k u_{n+1}^T A u_{n+1} = k u_{n+1}^T C u_n + u_{n+1}^T u_n. \tag{2.3}$$

Since $A \succeq C$, we have that

$$u_{n+1}^T u_{n+1} + k u_{n+1}^T C u_{n+1} \leq u_{n+1}^T u_n + k u_{n+1}^T C u_n. \tag{2.4}$$

Define $w = (u_{n+1}, k^{1/2}C^{1/2}u_{n+1})^T, v = (u_n, k^{1/2}C^{1/2}u_n)^T$. Then (2.4)) can be written as $w^T w \leq w^T v$. Applying the Cauchy-Schwarz inequality, we get $\|w\|_2 \leq \|v\|_2$. Hence,

$$u_{n+1}^T u_{n+1} + k u_{n+1}^T C u_{n+1} \leq u_n^T u_n + k u_n^T C u_n \tag{2.5}$$

or

$$\|u_{n+1}\|_E \leq \|u_n\|_E .\Box$$

The conclusion of the preceding theorem is that when (1.1) is homogeneous, $f \equiv 0$, we obtain that $\|u_n\|_E \neq \|u_0\|_e$, $\forall n$, independent of T. This means that our method is, indeed, unconditionally stable.

Consider (1.3) with $f \equiv 0$, rewritten as

$$(I + kA + kB_n)u_{n+1} = (I + kC)u_n, B_n = B(u_n). \tag{2.6}$$

Equation (2.6) yields

$$u_{n+1} = (I + kA + kB_n)^{-1}(I + kC)u_n,$$

which, in turn, implies that

$$(I + kC)^{\frac{1}{2}}u_{n+1} = (I + kC)^{\frac{1}{2}}(I + kA + kB_n)^{-1}(I + kC)^{\frac{1}{2}}(I + kC)^{\frac{1}{2}}u_n.$$

Therefore, from the definition of $\|\cdot\|_E$, a sufficient condition to prove the unconditional stability result is to prove that

$$\left\|(I + kC)^{\frac{1}{2}}(I + kA + kB_n)^{-1}(I + kC)^{\frac{1}{2}}\right\|_2 \leq 1.$$

From 1.2, this can be done by using the following Lemma.

Lemma 2.3. *Let $D_1 = {D_1}^T \succ 0$ and $D_2 = {D_2}^T \succ 0$ be $n \times n$ matrices such that $D_1 - D_2 \succ 0$. Let $D_4 = D_2^{\frac{1}{2}}$ and be symmetric. If D_3 is an $n \times n$ skew-symmetric matrix, then*

$$\| D_4(D_1 + D_3)^{-1}D_4 \|_2 \leq 1. \tag{2.7}$$

Proof: Let $F = D_4(D_1 + D_3)^{-1}D_4$. It is straightforward that $F^{-1} = D_4^{-1}(D_1 + D_3)D_4^{-1}$. For any nonzero vector x in $\Re^n$,

$$\begin{aligned} x^T F^{-1} x &= x^T D_4^{-1}(D_1 + D_3)D_4^{-1}x \\ &= x^T D_4^{-1} D_1 D_4^{-1} x + x^T D_4^{-1} D_3 D_4^{-1} x \end{aligned}$$

Here we claim that $D_4^{-1}D_3D_4^{-1}$ is skew symmetric and therefore $x^T D_4^{-1}D_3D_4^{-1}x = 0$. To obtain this one can notice that since $D_2 = D_4^2$ and D_2 is a symmetric matrix, then D_4 and D_4^{-1} are also symmetric.
Hence,

$$(D_4^{-1}D_3D_4^{-1})^T = D_4^{-1}D_3^T D_4^{-1} = -D_4^{-1}D_3D_4^{-1}.$$

Thus

$$x^T F^{-1}x = x^T D_4^{-1}D_1D_4^{-1}x, \qquad \text{for any } \; 0 \neq x \in \Re^n.$$

Using the fact that $D_1 - D_2$ is nonnegative, we obtain

$$x^T F^{-1}x \geq x^T D_4^{-1}D_2D_4^{-1}x = x^T x, \qquad \text{for any } \; 0 \neq x \in \Re^n.$$

This implies that

$$\|x\|_2^{\,2} \leq x^T F^{-1}x \leq \|x\|_2 \cdot \left\|F^{-1}x\right\|_2, \qquad \text{for any } \; 0 \neq x \in \Re^n,$$

that is,

$$\|x\|_2 \leq \left\|F^{-1}x\right\|_2, \qquad \text{for any } \; 0 \neq x \in \Re^n. \tag{2.8}$$

Obviously (2.8) is equivalent to

$$\|Fy\|_2 \leq \|y\|_2, \qquad \text{for any } \; 0 \neq y \in \Re^n. \tag{2.9}$$

Since the last equation holds for any nonzero vector y, then $\|F\|_2 \leq 1$.
□

For the next step, we analyze the stability of the nonhomogenous problem over an arbitrary but finite time interval $[0, T]$. We later show that the stability of the homogeneous problem does not depend on T. Consider (1.3) with $f \not\equiv 0$.

After some simple calculations, we get that u_n satisfies

$$u_{n+1} = (I + kA + kB_n)^{-1}(I + kC)u_n + k(I + kA + kB_n)^{-1}f_{n+1}. \tag{2.10}$$

We denote the range of the step index n, by $[0, N]$, where $kN = T$. To simplify the notation, we do not explicitly indicate that N depends on k and T.

Theorem 2.2. *Let (1.2) hold. Then the solution of (2.10) satisfies the following bound:*

$$\begin{aligned}\|u_{n+1}\|_E &\leq \|u_0\|_E + \frac{k}{1+k\lambda_{min}(C)}\Sigma_{p=0}^{n}\|f_{p+1}\|_E \\ &\leq \|u_0\|_E + \frac{T}{(1+k\lambda_{min}(C))}\max_{t\in[0,T]}\|f(t)\|_E\,,\ \forall 0\leq n\leq N-1.\end{aligned}$$

Here T is the size of the integration interval.

Proof: To simplify notation, we take $N_k = (I+kC)^{\frac{1}{2}}$ and $M_k = (I+kA+kB_n)^{-1}(I+kC)$. Then the equation (2.10) can be written as

$$u_{n+1} = M_k u_n + k(I+kA+kB_n)^{-1}f_{n+1}.$$

Using the definition 2.1, we have

$$(N_k u_{n+1})^T(N_k u_{n+1}) = (N_k u_{n+1})^T N_k M_k u_n + k(N_k u_{n+1})^T N_k (I+kA+kB_n)^{-1}f_{n+1}.$$

Algebraic manipulation and the Cauchy-Schwarz inequality yield

$$\begin{aligned}\|N_k u_{n+1}\|_2^{\,2} &\leq \|N_k u_{n+1}\|_2 \cdot \left\|N_k M_k N_k^{-1}\right\|_2 \cdot \|N_k u_n\|_2 \\ &\quad + k\,\|N_k u_{n+1}\|_2 \cdot \left\|N_k M_k N_k^{-1}\right\|_2 \cdot \left\|N_k^{-1} f_{n+1}\right\|_2.\end{aligned}$$

Using Lemma 2.3 with $D_2 = N_k^2$ and $D_1 + D_3 = M_k N_k^{-2}$, we obtain that $\left\|N_k M_k N_k^{-1}\right\|_2 \leq 1$. Then the previous inequality reduces to

$$\|N_k u_{n+1}\|_2 \leq \|N_k u_n\|_2 + k\left\|N_k^{-1} f_{n+1}\right\|_2$$

This inequality can be simplified as follows:

$$\begin{aligned}\|N_k u_{n+1}\|_2 &\leq \|N_k u_n\|_2 + k\left\|N_k^{-2} N_k f_{n+1}\right\|_2 \\ &\leq \|N_k u_n\|_2 + k\left\|(I+kC)^{-1}\right\|_2 \|N_k f_{n+1}\|_2 \\ &\leq \|N_k u_n\|_2 + \frac{k}{(1+k\lambda_{min}(C))}\|N_k f_{n+1}\|_2\,.\end{aligned}$$

Thus,

$$\|u_{n+1}\|_E - \|u_n\|_E \leq \frac{k}{(1+k\lambda_{min}(C))}\|f_{n+1}\|_E\,,$$

and since $(I+kC)^{-1}$ is a symmetric positive definite matrix,

$$\|I+kC\|_2 = \max \lambda(I+kC)^{-1} = \frac{1}{(\min \lambda(I+kC))}.$$

By the spectral mapping theorem $\lambda(I+kC) = 1+k\lambda(C)$. Therefore

$$\left\|(I+kC)^{-1}\right\|_2 = \frac{1}{1+k\lambda_{min}(C)},$$

where $\lambda_{min}(C)$ is the minimum eigenvalue of matrix C. This implies

$$\|u_{n+1}\|_E - \|u_n\|_E \leq \frac{k}{(1+k\lambda_{min}(C))} \|f_{n+1}\|_E, \; 0 \leq n \leq N-1.$$

Summing from 0 to n gives

$$\|u_{n+1}\|_E - \|u_0\|_E \leq \frac{k}{(1+k\lambda_{min}(C))} \Sigma_{p=0}^{n} \|f_{p+1}\|_E, \; \forall 0 \leq n \leq N-1,$$

that is,

$$\|u_{n+1}\|_E \leq \|u_0\|_E + \frac{k}{(1+k\lambda_{min}(C))} \Sigma_{p=0}^{n} \|f_{p+1}\|_E, \; 0 \leq n \leq N-1,$$

which is the claimed first result. The second result follows immediately. □

The local truncation error of the method (1.3) is clearly $O(\Delta t)$. In the error estimate (which follows) we need a precise statement of this fact, which we now derive.

To simplify our notation, we use u_n to denote $u(t_n)$, where $u(\cdot)$ is the exact solution of (1.1). We also use u_n to denote an iterate of our numerical scheme, but the particular meaning of u_n will become evident from the context.

According to the definition of local truncation error [**?**],

$$\begin{aligned} \tau_{n+1} &= \frac{u(t_{n+1})-u(t_n)}{k} + Au(t_{n+1}) + B(u(t_n))u(t_{n+1}) - Cu(t_n) \\ &\quad -[u'(t_{n+1}) + Au(t_{n+1}) + B(u(t_{n+1}))u(t_{n+1}) - Cu(t_{n+1})] \qquad (2.11) \\ &= \frac{u_{n+1}-u_n}{k} - u'_{n+1} - (B(u(t_{n+1})) - B(u(t_n)))u(t_{n+1}) + C(u_{n+1}-u_n). \end{aligned}$$

Using the second-order integral form of the Taylor expansion around t_{n+1}, we obtain

$$u_{n+1} - u_n - ku'_{n+1} = -\int_{t_{n+1}}^{t_n} u''(t)(t-t_{n+1})dt,$$

which we rewrite as

$$\frac{u_{n+1}-u_n}{k} - u'_{n+1} = -\frac{1}{k}\int_{t_{n+1}}^{t_n} u''(t)(t-t_{n+1})dt = -\frac{1}{k}\int_{t_n}^{t_{n+1}} u''(t)(t_{n+1}-t)dt.$$

Using the first-order integral form of the Taylor expansion around t_n, we obtain

$$\begin{array}{l}(B(u(t_{n+1})) - B(u(t_n)))u(t_{n+1}) - C(u_{n+1}-u_n) = \\ \int_{t_n}^{t_{n+1}} \left(\frac{d}{dt}B(u(t))u(t_{n+1}) - Cu'(t)\right) dt.\end{array}$$

Using the expression we have derived for the local truncation error τ_{n+1}, and the preceding equations derived from Taylor's theorem, we obtain

$$\begin{aligned}\tau_{n+1} &= -\frac{1}{k}\int_{t_n}^{t_{n+1}} u''(t)(t_{n+1}-t)dt - \int_{t_n}^{t_{n+1}} \left(\frac{d}{dt}B(u(t))u(t_{n+1}) - Cu'(t)\right) dt \\ &= \int_{t_n}^{t_{n+1}} \left(-\frac{t_{n+1}-t}{k}u''(t) - \frac{d}{dt}B(u(t))u(t_{n+1}) + Cu'(t)\right) dt.\end{aligned}$$

By the mean value theorem, there exists $\xi_n \in (t_n, t_{n+1})$ such that

$$\tau_{n+1} = -u''(\xi_n)(t_{n+1}-\xi_n) - k\left.\frac{d}{dt}B(u(t))\right|_{t=\xi_n} u(t_{n+1}) + kCu'(\xi_n). \quad (2.12)$$

Hence, using the fact that $0 \le (t_{n+1}-\xi_n) \le k$, we obtain that

$$\|\tau_{n+1}\|_2 \le k \max_{t_n \le s \le t_{n+1}} \left(\|u''(s)\|_2 + \left\| \left.\frac{d}{dt}B(u(t))\right|_{t=s} \right\|_2 \max_{t_n \le \theta \le t_{n+1}} \|u(\theta)\|_2 + \|Cu'(s)\|_2 \right).$$

This proves the following lemma.

Lemma 2.4. *Let $k = \Delta t$ and $n \ge 0$. The method*

$$\frac{u_{n+1}-u_n}{k} + Au_{n+1} + B_n u_{n+1} - Cu_n = f_{n+1}, \quad (2.13)$$

where $A = A^T \succ 0$ and $C = C^T \succeq 0$ are $n \times n$ symmetric matrices, B_n an $n \times n$ skew-symmetric matrix, and $f_{n+1} = f((n+1)k)$, is consistent. That is, the local truncation error is $O(\Delta t)$.

We now bound the total error. We consider first the energy norm of truncation error.

Lemma 2.5. *Let τ_{n+1} be the local truncation error of method (2.13). Then*

$$\|\tau_{n+1}\|_E \leq k \max_{0\leq t\leq T} \left(\|u''(t)\|_E + \|Cu'(t)\|_E + \left\| \frac{d}{dt} B(u(t)) \right\|_E \max_{0\leq s\leq T} \|u(s)\|_E \right). \tag{2.14}$$

Proof: By definition of energy norm and following the identity (2.12), we get

$$\|\tau_{n+1}\|_E = \left\| -u''(\xi_n)(t_{n+1} - \xi_n) - k \left. \frac{d}{dt} B(u(t)) \right|_{t=\xi_n} u(t_{n+1}) + kCu'(\xi_n) \right\|_E$$

for some $\xi_n \in [t_n, t_{n+1}]$. The conclusion follows after applying the inequality $0 \leq t_{n+1} - \xi_n \leq k$, the triangle inequality, and the properties of the max function. Note that $\left\| \frac{d}{dt} B(u(t)) \right\|_E$ is the induced $\|\cdot\|_E$ of the corresponding matrix. $\square$

We now give a convergence result for the solution of (1.3). First, we need to compute a certain estimate. We have that

$$[B(u(t_n)) - B(u_n)]\, u(t_{n+1}) = \int_0^1 \frac{d}{d\theta} [B(u(t_n)\theta + u_n(1-\theta))] u(t_{n+1}) dt =$$
$$(\nabla_u (B(u(t_n)\theta_n + u_n(1-\theta_n))) e_n)\, u(t_{n+1}), \quad \text{for some } \theta_n \in [0,1],$$

where $e_n = u(t_n) - u_n$. Here $u(t_n)$ is the solution of (1.1), whereas u_n is the solution of our numerical scheme.

We define the matrix W_n, by its action on a vector $x \in \Re^n$:

$$W_n x = [(\nabla_u B(u(t_n)\theta_n + u_n(1-\theta_n)))\, x]\, u(t_{n+1}),$$

which results in the following identity

$$[B(u(t_n)) - B(u_n)]\, u(t_{n+1}) = W_n e_n. \tag{2.15}$$

Lemma 2.6. *Let u(.) be the solution of (1.1) and u_n be the approximation to $u(n\Delta t)$, obtained from the numerical scheme (1.3). Then there exists Γ such that, $\forall t \in [0,T]$ we have that*

$$\|W_n\|_2 \leq \Gamma, \text{ and } \|W_n\|_E \leq \Gamma_E = \Gamma\sqrt{1 + k\lambda_{max}(C)}, \ \forall 0 \leq n \leq N.$$

Proof: From Theorem 2.2 we have that

$$\begin{aligned}\|u_n\|_2 &\leq \|u_n\|_E \leq \|u_0\|_E + T\max_{t\in[0,T]}\|f(t)\|_E \\ &\leq \sqrt{1+k\lambda_{max}(C)}\left(\|u_0\|_2 + T\max_{t\in[0,T]}\|f(t)\|_2\right),\ \forall 0\leq n\leq N.\end{aligned}$$

We define

$$\Lambda_E = \sqrt{1+T\lambda_{max}(C)}\left(\|u_0\|_2 + T\max_{t\in[0,T]}\|f(t)\|_2\right).$$

From Lemma 2.1 we have that $u(t)$ is bounded on $[0,T]$, and we define $\Lambda_u = \max_{t\in[0,T]}\|u(t)\|_2$. Since $B(\cdot)$ is of class C^1, we can define

$$\Gamma = \max_{\theta\in[0,1],\,\|u_1\|_2\leq\Lambda_E,\,\|u_2\|_2=1,\,\|v_1\|\leq\Lambda_u,\|v\|_2\leq\Lambda_u} \|[(\nabla_u B(\theta v_2+(1-\theta)u_1))\,u_2]\,v_1\|_2\,.$$

From the definition of W_n, we immediately obtain that

$$\|W_n\|_2 \leq \Gamma,\ \forall 0\leq n\leq N.$$

The second part of the conclusion follows from the inequality between $\|\cdot\|_E$ and $\|\cdot\|_2$. □

Theorem 2.3. *Consider solving the nonhomogenous problem on the interval [0,T]*

$$u' + Au + B(u)u - Cu = f$$

using the following method

$$\frac{u_{n+1}-u_n}{k} + Au_{n+1} + B_n u_{n+1} - Cu_n = f_{n+1},$$

where $k=\Delta t$, $B_n = B(u_n)$ and $f_{n+1} = f((n+1)k)$. Let $e_n = u(t_n) - u_n$ denote the local error. Assume that $e_0 = 0$. Then the method is convergent and

$$\begin{aligned}\|e_{n+1}\|_E &\leq \frac{\left(1+\frac{k\Gamma_E}{1+k\lambda_{min}(C)}\right)^{n-1}-1}{1+\frac{k\Gamma_E}{1+k\lambda_{min}(C)}}\frac{k^2U}{1+k\lambda_{min}(C)} \\ &\leq \frac{e^{\frac{T\Gamma_E}{1+k\lambda_{min}(C)}}-1}{1+\frac{k\Gamma_E}{1+k\lambda_{min}(C)}}\frac{k^2U}{1+k\lambda_{min}(C)},\ \forall 0\leq n\leq N-1,\end{aligned}$$

when $\Gamma_E \neq 0$, *and*

$$\|e_{n+1}\|_E \leq (n+1)\frac{k^2 U}{1+k\lambda_{min}(C)} \leq T\frac{kU}{1+k\lambda_{min}(C)}, \forall 0 \leq n \leq N-1,$$

when $\Gamma_E = 0$, *where*

$$U = \max_{0\leq t\leq T}\left(\|u''(t)\|_E + \|Cu'(t)\|_E + \left\|\frac{d}{dt}B(u(t))\right\|_E \max_{0\leq s\leq T}\|u(s)\|_E\right).$$

Proof: Following the definition of the truncation error τ_{n+1} and using the equation (2.15), we obtain that the error, $e_n = u(t_n) - u_n$, satisfies

$$\frac{e_{n+1}-e_n}{k} + Ae_{n+1} + B_n e_{n+1} - Ce_n = \tau_{n+1} - W_n e_n.$$

After algebraic calculations, we find that

$$e_{n+1} = (I+kA+kB_n)^{-1}(I+kC)e_n + k(I+kA+kB_n)^{-1}(\tau_{n+1} - W_n e_n).$$

We use the energy inner product to obtain

$$< e_{n+1}, e_{n+1} >_E =$$
$$< (I+kA+kB_n)^{-1}(I+kC)e_n + k(I+kA+kB_n)^{-1}(\tau_{n+1} - W_n e_n), e_{n+1} >_E .$$

Applying the definition of energy norm (2.1) and the substitutions $M_k = (I+kA+kB_n)^{-1}(I+kC)$, and $N_k = (I+kC)^{\frac{1}{2}}$, we find that

$$(N_k e_{n+1})^T (N_k e_{n+1}) =$$
$$(N_k e_{n+1})^T N_k M_k e_n + k(N_k e_{n+1})^T N_k (I+kA+kB_n)^{-1})(\tau_{n+1} - W_n e_n).$$

Using the Cauchy-Schwarz inequality, we obtain that

$$\begin{aligned}\|N_k e_{n+1}\|_2^2 \;\leq\; & \|N_k e_{n+1}\|_2 \cdot \left\|N_k M_k N_k^{-1}\right\|_2 \cdot \|N_k e_n\|_2 \\ & + k\,\|N_k e_{n+1}\|_2 \cdot \left\|N_k M_k N_k^{-1}\right\|_2 \cdot \left\|N_k^{-1}(\tau_{n+1} - W_n e_n)\right\|_2 .\end{aligned}$$

Thus

$$\|N_k e_{n+1}\|_2 \leq \left\|N_k M_k N_k^{-1}\right\|_2 \cdot \|N_k e_n\|_2 + k\left\|N_k M_k N_k^{-1}\right\|_2 \cdot \left\|N_k^{-1}(\tau_{n+1} - W_n e_n)\right\|_2 .$$

Using Lemma 2.3 with $D_2 = N_k^2$ and $D_1 + D_3 = M_k N_k^{-2}$, we obtain that $\left\|N_k M_k N_k^{-1}\right\|_2 \leq 1$. Hence

$$\|e_{n+1}\|_E \leq \|e_n\|_E + k\left\|N_k^{-2}\right\|_2 \|(\tau_{n+1} - W_n e_n)\|_E .$$

Equivalently, we obtain that

$$\|e_{n+1}\|_E \leq \|e_n\|_E + k \left\|(I+kC)^{-1}\right\|_2 (\|\tau_{n+1}\|_E + \|W_n\|_E \|e_n\|_E).$$

Notice that $(I+kC)^{-1}$ is a symmetric positive definite matrix and

$$\left\|(I+kC)^{-1}\right\|_2 = \frac{1}{1+k\lambda_{min}(C)}.$$

On the other hand, by Lemma 2.6, there is a constant Γ_E such that $\|W_n\|_E \leq \Gamma_E$. Therefore,

$$\|e_{n+1}\|_E \leq \left(1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}\right) \|e_n\|_E + \frac{k}{1+k\lambda_{min}(C)} \|\tau_{n+1}\|_E . \quad (2.16)$$

This is a recursion formula of the following form:

$$r_{n+1} \leq a r_n + b\tau_n,$$

which, when $a \neq 0$ has an upper bound of the type

$$r_{n+1} \leq a^n r_0 + \frac{a^{n-1}-1}{a} b \max_n \|\tau_n\|_E .$$

Using this fact, we obtain that, when $\Gamma_E \neq 0$, the following bound for the error holds whenever $0 \leq n \leq N-1$.

$$\begin{aligned} \|e_{n+1}\|_E \quad \leq \quad & \left(1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}\right)^n \|e_0\|_E \\ & + \frac{\left(1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}\right)^{n-1} - 1}{1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}} \cdot \frac{k}{1+k\lambda_{min}(C)} \max_n \|\tau_{n+1}\|_E \end{aligned}$$

Replacing $\|\tau_{n+1}\|_E$ by its bound (2.14) obtained in Lemma 2.5, and considering that $e_0 = 0$, we have, when $\Gamma_E \neq 0$ and $0 \leq n \leq N-1$, that

$$\|e_{n+1}\|_E \leq \frac{\left(1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}\right)^{n-1} - 1}{1 + \frac{k\Gamma_E}{1+k\lambda_{min}(C)}} \cdot \frac{k^2 U}{1+k\lambda_{min}(C)}$$

with $U = \max_{0\le t\le T}\left(\|u''(t)\|_E + \|Cu'(t)\|_E + \left\|\frac{d}{dt}B(u(t))\right\|_E \max_{0\le s\le T}\|u(s)\|_E\right)$. The second inequality for $\Gamma \neq 0$ follows from the inequality $(1+x)^n \le e^{xn}$, for $x > 0$ and n positive integer.

When $\Gamma_E = 0$, we immediately get from (2.16) and from Lemma 2.5 that

$$\|e_{n+1}\|_E \le (n+1)\frac{k^2 U}{1 + k\lambda_{min}(C)},\ \forall 0 \le n \le N-1,$$

which, together with $kN = T$ prove the inequalities for $\Gamma_E = 0$.

The convergence follows from the fact that $\|\cdot\|_E$ converges to $\|\cdot\|_2$ as $k \to 0$ which implies that $\|e_n\|_2 \to 0$ as $k \to 0$. □

The case $\Gamma_E = 0$ occurs, for example, when $B(u)$ is constant (which we simulate numerically in the next section). For that case, the error increases only linearly with the size of the interval, assuming that the derivatives up to order 2 of the solution $u(t)$ are uniformly bounded.

3 Numerical Results

Let $\Omega = [0,1] \times [0,1]$. For the equation

$$\begin{aligned} u_t + b\cdot\nabla u - \epsilon\Delta u &= f, \text{ over } \Omega, \\ u &= \phi(x) \text{ on } \delta\Omega, \\ u(x,0) &= u_0(x) \text{ in } \Omega, \end{aligned} \tag{3.1}$$

use the method described in this work, with uniform mesh and central difference. A choice must be made for the antidiffusion operator: averaging or projection. We have selected averaging. Since it is just outside the theory, we will thereby test the robustness of the algorithm. Antidiffusion is completed by averaging, where $\bar{u}(p)$:=weighted average of nearest neighbors. This corresponds to filtering with $\delta = 2h$. The method becomes in our case

$$\dot{u}_{ij}(t) + b\cdot\nabla^h u_{ij} - (\epsilon+\epsilon_0)\Delta^h u_{ij} + \epsilon_0\overline{\Delta\overline{u_{ij}}}^q = h,$$

where q denotes how many times the average operation is taken. In our experiments we chose $q = 2$ and $\epsilon = 10^{-4}$. We take $b = (\cos(\theta), \sin(\theta))$, where $\theta = 17°$.

For the boundary and initial conditions we take the line at angle θ through the center of the domain. On the north side of the line we take $\phi = 1$ on the

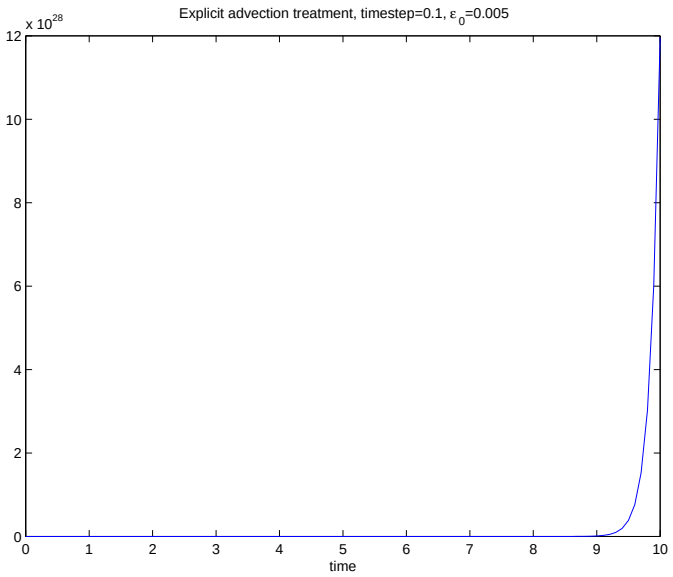

Figure 4: Exponential growth of the solution of the scheme that includes the advection term explicitly

boundary; on the south side we take $\phi = 0$ on the boundary. We take $f = 0$ and 0 as initial conditions.

We performed the following experiments, all on a 32×32 mesh.

1. We ran the simulation for $1,000$ steps with a timestep of 10, with the artificial viscosity parameter ϵ_0 having succesively the values 10^{-1}, 5×10^{-3}, 10^{-3}, 10^{-4}. We have presented no analysis for the spatial dependence of the solution with respect to ϵ_0, but we have included this experiment for validation, since our choice of parameters should result roughly in the steady-state approximation for this mesh, which has been studied before in the literature.

   The results are depicted in Figure 1. We see that when the artificial viscosity parameter ϵ_0 is very small, a complete loss of coherence of the spatial structure results, whereas too large a parameter ($\epsilon_0 = 0.1$) alters the steady-state solution significantly. This effect is consistent with the typical behavior of centered methods for the skew step problem [**?**].

2. For $\epsilon_0 = 10^{-4}$, we ran the simulation for 100 steps with a timestep of 1 and for $1,000$ steps with a timestep of 0.1. The energy norm comparison

of these computations is presented in Figure 2. We see that even for the very large step, the energy norm stays bounded, consistent with our absolute stability claim.

We also present in Figure 3 a comparison between the energy norms of the distance between the successive iterates of the two cases and their outcome at time 100. From Figure 2, we infer that $u(100)$ is a reasonable approximation to the steady-state solution. Since the equation (3.1) is linear, we have that $u_n - u(100)$ is the result of the numerical scheme applied to the homogeneous equation associated to (3.1). From Theorem 2.1 we have that $\|u_n - u(100)\|_E$ must be a decreasing sequence, which is exactly what we observe from Figure 3. Note that $\|u_n\|_E$ is not a decreasing sequence, as can be seen in Figure 3. Moreover, the sequence $\|u_n\|_E$ may not even be monotonic, as seen in Figure 2, for $k = 0.1$.

3. We compare the results of our scheme with the similar scheme that takes into account explicitly the term that contains the skew-symmetric matrix $B(u_n)$. For the latter scheme we obtain the recursion

$$\frac{u_{n+1} - u_n}{k} + Au_{n+1} + B(u_n)u_n - Cu_n = f_{n+1}.$$

We apply this scheme to our example on a 32×32 mesh for 1000 timesteps of length $k = 1$. We see the rapid exponential growth that is typical for computations with the timestep outside the region of stability.

This demonstrates that our scheme has significantly better stability properties than the alternative, which would result in linear systems of comparable sparsity. The numerical scheme, based on a backward Euler approach that considers all terms implicitly, though absolutely stable, will result in less sparse linear systems since the matrix C contains an averaging operator that substantially reduces sparsity and is not considered here for comparison.
